microSD Card

The microSD format was created by SanDisk. It is the smallest memory card available commercially; at $15 \times 11 \times 1$ mm (about the size of a fingernail), it is about a quarter the size of a standard-sized SD card. TransFlash and microSD cards are the same (each can be used in devices made for the other), except that microSD adds support for SDIO mode, enabling non-memory cards like Bluetooth, GPS, and Near Field Communication devices.

microSD cards with a memory capacity larger than 2 GB are microSDHC, which uses the exact same technology as SDHC, just in the smaller microSD size. The "HC" stands for "high capacity."

- Small Size (15mm x 11mm)
 - High Storage Capacity (SDHC)
 - High performance (SD Class 6)
 - Can use 4-bit SD or SPI access modes
 - Full boot capability
 - Automatic wear leveling
 - Hot Swappable
 - Cost effective solution
 - Low power consumption (near zero when idle, typically 45mA during transfers, max of about 100mA)
 - Compatible with all of EMAC boards using a SD/MMC Socket
 - Compatible with all Embedded Operating Systems such as EMAC Linux/Real Time Linux, DOS, WinCE, and XP Embedded.
